Hyponatremia in Older Adults: Diagnosis
Sangeetha Murugapandian, M.D. and Bijin Thajudeen, M.D.; Department of Medicine, University of Arizona

Prevalence
Hyponatremia, defined as serum sodium level less than 135mEq/L, is one of the most common electrolyte abnormalities seen in older adults. In one study, more than 50% of patients in acute geriatric wards were found to have hyponatremia. Chronic hyponatremia has been reported in 18% of nursing home residents.

Why is the Prevalence Increased in Older Adults?
A number of factors contribute to the high prevalence of hyponatremia in older adults (Table 1.)

Why is Hyponatremia Important?
Long-standing or slowly developing chronic hyponatremia may be asymptomatic but is associated with increased osteoclastic activity leading to bone demineralization and fractures. Symptoms of acute hyponatremia vary depending on the degree of hyponatremia and rapidity with which it develops (Table 2). Those with severe acute hyponatremia can develop cerebral edema. Less severe cases are associated with confusion, functional and cognitive decline, and gait disturbances that can lead to falls. Patients with hyponatremia also have increased mortality rates and longer hospitalizations.

What Causes Hyponatremia?
Depending on a patient’s volume status, hyponatremia is classified hypovolemic (low fluid volume status), euovolemic (normal volume status) or hypervolemic (increased volume status). Common causes of each of these forms of hyponatremia are shown in Table 3, but in older adults, the cause is often multifactorial. The algorithm (next page) and the items in Table 4 show the general approach to identifying the cause.

TIPS ABOUT HYPONATREMIA IN OLDER ADULTS
- Hyponatremia, one of the most common electrolyte abnormalities in older adults, is associated with falls, cognitive decline, osteoporosis, fractures, and increased hospital stays and mortality rates. Acute changes are associated with more severe symptoms; severe acute hyponatremia can cause cerebral edema and brainstem herniation.
- Be sure to ask about whether the patient is taking medications associated with hyponatremia (see Table 1).
- Key factors determining the cause of hyponatremia are a patient’s volume status (hypovolemic, euvoeemic, or hypervolemic) and measurements of serum osmolality and urine osmolality (see algorithm).
Table 4. Components of the History and Physical in Older Adults with Hyponatremia to Aid in Identifying the Cause

<table>
<thead>
<tr>
<th>Review Hospital Records</th>
<th>Use of hypotonic fluids, medications, surgical history, pain assessment, recent interventions (transurethral resection of prostate, use of hypertonic fluids)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Medical History</td>
<td>Vomiting, diarrhea, heart failure, pulmonary disease, liver disease, renal failure, thyroid, neurological disorders, falls, cognitive impairment, adrenal disorders</td>
</tr>
<tr>
<td>Medication Use</td>
<td>Diuretics, SSRIs, neuroleptics (anti-psychotics), carbamazepine, and amiodarone are common causes. But, check prescribing information for all medication a patient is taking to determine potential to cause hyponatremia.</td>
</tr>
<tr>
<td>Social History</td>
<td>Living conditions, diet, alcohol</td>
</tr>
<tr>
<td>Psychiatric History</td>
<td>Abnormal water intake</td>
</tr>
<tr>
<td>Assessment of Volume Status</td>
<td>Signs of hypervolemia = peripheral edema, pulmonary rales</td>
</tr>
<tr>
<td></td>
<td>Signs of hyponatremia = orthostatic hypotension, tachycardia, dry axillae</td>
</tr>
</tbody>
</table>
